

ABSTRACT

The present invention describes a method and system for creating and exposing order status within a supply chain of trading partners having disparate systems. A trading partner exchange (TPE) interfaces with each of the disparate systems and gathers information pertaining to a particular transaction. The information can be made available to an access platform through an access platform interface. Initially, a transaction is reported to the TPE where it is assigned a unique identifier. Subsequent activities pertaining to the transaction which are reported to the TPE by the trading partners can be linked to the unique identifier. By using the access platform, a customer or any trading partner can acquire the status of a particular order from the TPE.
